

Eichler-Shimura isomorphism

Arun Soor

3rd November 2022

Abstract

These are notes for a seminar on Galois representations and modularity given in November 2022.

1 Preliminaries

Let \mathfrak{H} denote the complex upper half plane and let $\mathfrak{H}^* = \mathfrak{H} \cup (\mathbb{Q} \cup \{\infty\})$ be the extended upper half plane obtained by adding in the cusps. Then $\mathfrak{H}, \mathfrak{H}^*$ have an action of $\mathrm{SL}_2(\mathbb{Z})$ by fractional linear transformations. Let $\Gamma \leq \mathrm{SL}_2(\mathbb{Z})$ be a congruence subgroup. The quotients

$$Y := \Gamma \backslash \mathfrak{H} \quad X := \Gamma \backslash \mathfrak{H}^*, \quad (1)$$

have a natural complex structure under which X becomes a compact Riemann surface. A modular form of weight k and level Γ is a holomorphic function on \mathfrak{H} satisfying a boundedness condition at the cusps and the transformation rule

$$f|_k \gamma(\tau) := j(\gamma, \tau)^{-k} f(\gamma(\tau)) = f(\tau), \text{ for all } \gamma \in \Gamma, \quad (2)$$

where, for $\gamma = \begin{pmatrix} * & * \\ c & d \end{pmatrix} \in \Gamma$, $j(\gamma, \tau) := (c\tau + d)$ is the “factor of automorphy”. They form a vector space $\mathcal{M}_k(\Gamma)$. If f vanishes at the cusps it is called a cusp form and the subspace of such is denoted $\mathcal{S}_k(\Gamma)$. We can form the line bundle $\Gamma \backslash (\mathfrak{H} \times \mathbb{C}) \xrightarrow{p} Y$, with the natural projection p from the first factor, where Γ acts on $\mathfrak{H} \times \mathbb{C}$ by $\gamma \cdot (\tau, z) = (\gamma(\tau), j(\gamma, \tau)^k z)$. This extends to a line bundle ω^k over X . For f a holomorphic function on \mathfrak{H} , the condition that $\tau \mapsto (\tau, f(\tau))$ is a holomorphic section of p is equivalent to the rule (2), and boundedness of f at the cusps is equivalent to this section extending to X . Therefore we identify

$$\mathcal{M}_k(\Gamma) = H^0(X, \omega^k), \quad \mathcal{S}_k(\Gamma) = H^0(X, \omega^k(-D)), \quad (3)$$

where $D = X - Y$ is the divisor defined by the cusps. There are \mathbb{Q} -schemes Y_Γ and X_Γ , where Y_Γ is affine, smooth, and identified with an open subscheme of the proper X_Γ , such that

$$Y = Y_\Gamma(\mathbb{C})^{\mathrm{an}} \quad \text{and} \quad X = X_\Gamma(\mathbb{C})^{\mathrm{an}}, \quad (4)$$

where, if the level of Γ is ≥ 3 , Y_Γ is the fine moduli scheme representing the moduli functor (on Sch/\mathbb{Q}),

$$Y_\Gamma(S) = \{\text{elliptic schemes } E/S/\mathbb{Q} \text{ with level } \Gamma \text{ structure}\} / \sim, \quad (5)$$

similarly X_Γ represents a moduli of generalised elliptic curves with level Γ structure. (The identification on $Y = Y_\Gamma(\mathbb{C})^{\text{an}}$ is by sending an elliptic curve to its period.) By Yoneda, there then exists a universal elliptic curve with level Γ structure \mathcal{E}_Γ over Y_Γ . Henceforth we shall ignore all discussion of cusps and abusively refer to \mathcal{E}_Γ over X_Γ .

2 Eichler-Shimura isomorphism

Let $\mathcal{E}_\Gamma \xrightarrow{\pi} X_\Gamma$ be the structure map. It is proper. Then $\omega := \pi_* \Omega_{\mathcal{E}/X}^1$ is a line bundle over X_Γ such that the sheaf induced by $\omega^{\otimes k}$ on $X = X_\Gamma(\mathbb{C})^{\text{an}}$ agrees with ω^k introduced previously. Therefore we have an ‘‘algebraic definition’’ of modular forms

$$\mathcal{M}_k(\Gamma) := H^0(X_\Gamma, \omega^{\otimes k}). \quad (6)$$

The relative de Rham cohomology $\mathcal{H}_{\text{dR}}^1(\mathcal{E}/X)$ is equipped with a decreasing Hodge filtration

$$0 \rightarrow \omega \rightarrow \mathcal{H}_{\text{dR}}^1(\mathcal{E}/X) \rightarrow \omega^{-1} \rightarrow 0 \quad (7)$$

and Gauss-Manin connection $\nabla : \mathcal{H}_{\text{dR}}^1(\mathcal{E}/X) \rightarrow \mathcal{H}_{\text{dR}}^1(\mathcal{E}/X) \otimes \Omega_{X_\Gamma}^1$ satisfying Griffiths transversality, which, in this situation, amounts to the map

$$\nabla : \omega = \text{gr}^1 \mathcal{H}_{\text{dR}}^1(\mathcal{E}/X) \rightarrow \text{gr}^0 \mathcal{H}_{\text{dR}}^1(\mathcal{E}/X) \otimes \Omega_{X_\Gamma}^1 = \omega^{-1} \otimes \Omega_{X_\Gamma}^1, \quad (8)$$

being well-defined. This is in fact an isomorphism, due to the Kodaira-Spencer isomorphism:

$$\omega^{\otimes 2} \cong \Omega_{X_\Gamma}^1, \quad (9)$$

One can see this on the Riemann surface $X = \Gamma \backslash \mathfrak{H}^*$ as the map given locally by $\Omega_X^1(U) \ni f(\tau)d\tau \mapsto f(\tau)$, which is then a weight 2 modular form because of the rule $d\gamma(\tau) = j(\gamma, \tau)^{-2}d\tau$, i.e., a section of ω^2 . Let $\underline{\mathbb{Z}}$ be the constant local system on \mathcal{E}_Γ . Then $R^1\pi_*\underline{\mathbb{Z}}$ is (non-canonically) isomorphic to the locally constant sheaf $\underline{\mathbb{Z}}^2$ on X_Γ . Therefore there are isomorphisms

$$\begin{aligned} H^1(\Gamma, \text{Sym}^{k-2}\mathbb{Z}^2) \otimes \mathbb{C} &\cong H_{\text{Betti}}^1(\mathfrak{H}^*/\Gamma, \text{Sym}^{k-2}\mathbb{Z}^2) \otimes \mathbb{C} \\ &= H^1(X_\Gamma(\mathbb{C})^{\text{an}}, \text{Sym}^{k-2}R^1\pi_*\underline{\mathbb{Z}}) \otimes \mathbb{C} \\ &= H^1(X_\Gamma(\mathbb{C})^{\text{an}}, \text{Sym}^{k-2}R^1\pi_*\underline{\mathbb{C}}_{\mathcal{E}}). \end{aligned} \quad (10)$$

Recall that the Riemann-Hilbert correspondence, for a smooth variety Z/\mathbb{C} is

$$\{\mathbb{C}\text{-local systems } \mathbb{L} \text{ on } Z(\mathbb{C})^{\text{an}}\} \leftrightarrow \left\{ \begin{array}{l} \mathcal{O}_Z\text{-modules with} \\ \text{integrable connection } (\mathcal{M}, \nabla) \end{array} \right\}, \quad (11)$$

under which $\underline{\mathbb{C}}_Z$ corresponds to \mathcal{O}_Z . Moreover if \mathbb{L} corresponds to (\mathcal{M}, ∇) one has $H^i(Z(\mathbb{C})^{\text{an}}, \mathbb{L}) = H_{\text{dR}}^i(Z, \mathcal{M})$. It extends to a derived equivalence between perverse sheaves and regular holonomic \mathcal{D} -modules, compatible with the six functors on both sides, such that we recover (11) by taking cohomology. In our situation this implies $R^1\pi_*\mathbb{C}$ corresponds to $\mathcal{H}_{\text{dR}}^1(\mathcal{E}/X)$ since this is the first cohomology of the \mathcal{D} -module pushforward

$\int_{\pi} \mathcal{O}_{\mathcal{E}}$. See [HTT08, Theorem 7.1.1]. Then, taking Sym^{k-2} , $\mathrm{Sym}^{k-2} R^1 \pi_* \mathbb{C}$ corresponds to $\mathrm{Sym}^{k-2} \mathcal{H}_{\mathrm{dR}}^1(\mathcal{E}/X)$. Therefore

$$H^1(X_{\Gamma}(\mathbb{C})^{\mathrm{an}}, \mathrm{Sym}^{k-2} R^1 \pi_* \underline{\mathbb{C}}_{\mathcal{E}}) \cong H_{\mathrm{dR}}^1(X_{\Gamma, \mathbb{C}}, \mathrm{Sym}^{k-2} \mathcal{H}_{\mathrm{dR}}^1(\mathcal{E}/X)). \quad (12)$$

From the convergence of the Hodge-de Rham spectral sequence,

$$E_1^{p,q} = H^p(X_{\Gamma, \mathbb{C}}, \Omega_{X_{\Gamma}}^q \otimes \mathrm{Sym}^{k-2} \mathcal{H}_{\mathrm{dR}}^1(\mathcal{E}/X)) \Rightarrow H_{\mathrm{dR}}^{p+q}(X_{\Gamma, \mathbb{C}}, \mathrm{Sym}^{k-2} \mathcal{H}_{\mathrm{dR}}^1(\mathcal{E}/X)), \quad (13)$$

we have an exact sequence of low degree terms

$$\begin{aligned} 0 \rightarrow H^0(X_{\Gamma, \mathbb{C}}, \mathrm{Sym}^{k-2} \mathcal{H}_{\mathrm{dR}}^1(\mathcal{E}/X)) &\rightarrow H^0(X_{\Gamma, \mathbb{C}}, \Omega_{X_{\Gamma}}^1 \otimes \mathrm{Sym}^{k-2} \mathcal{H}_{\mathrm{dR}}^1(\mathcal{E}/X)) \\ &\rightarrow H_{\mathrm{dR}}^1(X_{\Gamma, \mathbb{C}}, \mathrm{Sym}^{k-2} \mathcal{H}_{\mathrm{dR}}^1(\mathcal{E}/X)) \\ &\rightarrow H^1(X_{\Gamma, \mathbb{C}}, \mathrm{Sym}^{k-2} \mathcal{H}_{\mathrm{dR}}^1(\mathcal{E}/X)) \\ &\rightarrow H^1(X_{\Gamma, \mathbb{C}}, \Omega_{X_{\Gamma}}^1 \otimes \mathrm{Sym}^{k-2} \mathcal{H}_{\mathrm{dR}}^1(\mathcal{E}/X)) \rightarrow 0 \end{aligned} \quad (14)$$

Now examine the first two terms in the sequence. The last two terms will be essentially the same by Serre duality. Consider

$$\begin{array}{ccc} H^0(X_{\Gamma, \mathbb{C}}, \mathrm{Sym}^{k-2} \mathcal{H}_{\mathrm{dR}}^1(\mathcal{E}/X)) & \xrightarrow{\nabla_*} & H^0(X_{\Gamma, \mathbb{C}}, \mathrm{Sym}^{k-2} \mathcal{H}_{\mathrm{dR}}^1(\mathcal{E}/X) \otimes \Omega_{X_{\Gamma}}^1) \\ & & \uparrow \\ & & H^0(X_{\Gamma, \mathbb{C}}, \omega^{k-2} \otimes \Omega_{X_{\Gamma}}^1) \end{array} \quad (15)$$

where the vertical map is induced by the Hodge filtration (7) on $\mathcal{H}_{\mathrm{dR}}^1(\mathcal{E}/X)$ and the horizontal map ∇_* is induced by the Gauss-Manin connection ∇ . We claim that

$$\mathcal{S}_k(\Gamma) \cong H^0(X_{\Gamma, \mathbb{C}}, \omega^{k-2} \otimes \Omega_{X_{\Gamma}}^1) \text{ maps isomorphically onto } \mathrm{coker} \nabla_*, \quad (16)$$

where on the left we used the Kodaira-Spencer isomorphism. Indeed, the Hodge filtration on $\mathcal{H}_{\mathrm{dR}}^1(\mathcal{E}/X)$ induces one on $\mathrm{Sym}^{k-2} \mathcal{H}_{\mathrm{dR}}^1(\mathcal{E}/X)$, with

$$\mathrm{gr}^p \mathrm{Sym}^{k-2} \mathcal{H}_{\mathrm{dR}}^1(\mathcal{E}/X) \cong \omega^{2-k+2p}, \quad (17)$$

therefore, again by Kodaira-Spencer,

$$\mathrm{gr}^{\bullet} \nabla \text{ maps } \mathrm{gr}^p \mathrm{Sym}^{k-2} \mathcal{H}_{\mathrm{dR}}^1 \text{ isomorphically onto } \mathrm{gr}^{p-1} \mathrm{Sym}^{k-2} \mathcal{H}_{\mathrm{dR}}^1 \otimes \Omega_{X_{\Gamma}}^1, \quad (18)$$

for $p \geq k-2$. It follows that

$$\mathrm{coker} \mathrm{gr}^{\bullet} \nabla_* \cong H^0(X_{\Gamma, \mathbb{C}}, \omega^{k-2} \otimes \Omega_{X_{\Gamma}}^1)[2-k] = \mathrm{gr}^{\bullet} H^0(X_{\Gamma, \mathbb{C}}, \omega^{k-2} \otimes \Omega_{X_{\Gamma}}^1), \quad (19)$$

since on the right hand side the filtration only jumps in degree $k-2$. The claim now follows since gr^{\bullet} is a conservative functor. Putting this all together, (and doing the same, after Serre duality, for the last two terms in (14)), we have obtained a natural short exact sequence

$$0 \rightarrow \mathcal{S}_k(\Gamma) \xrightarrow{\delta} H_{\mathrm{dR}}^1(X_{\Gamma, \mathbb{C}}, \mathrm{Sym}^{k-2} \mathcal{H}_{\mathrm{dR}}^1(\mathcal{E}/X)) \rightarrow \mathcal{S}_k(\Gamma)^{\vee} \rightarrow 0, \quad (20)$$

The de Rham's theorem comparison

$$H_{\mathrm{Betti}}^1(X, \mathrm{Sym}^{k-2} \underline{\mathbb{Z}}^2) \otimes \mathbb{C} \cong H_{\mathrm{dR}}^1(X_{\Gamma, \mathbb{C}}, \mathrm{Sym}^{k-2} \mathcal{H}_{\mathrm{dR}}^1(\mathcal{E}/X)) \quad (21)$$

endows the middle term of (20) with a complex conjugation ι , from $\text{id} \otimes \overline{(-)}$ on the left side, under which (20) becomes a Hodge filtration in weights $(k-1, 0), (0, k-1)$. In particular $\overline{\delta} : \overline{\mathcal{S}_k(\Gamma)} \cong \mathcal{S}_k(\Gamma)^\vee \rightarrow H_{\text{dR}}^1(\dots)$ gives a splitting of the quotient map in (20) and hence, combining with β , an isomorphism

$$\beta : \mathcal{S}_k(\Gamma) \oplus \overline{\mathcal{S}_k(\Gamma)} \xrightarrow{\sim} H_{\text{Betti}}^1(X, \text{Sym}^{k-2}\mathbb{Z}^2) \otimes \mathbb{C}. \quad (22)$$

This is known as the Eichler-Shimura isomorphism.

3 Hecke operators

Let $\Gamma \leq \text{SL}_2(\mathbb{Z})$ be a congruence subgroup, let $\alpha \in \text{GL}_2(\mathbb{Q})$ and set

$$\Gamma^\alpha = \alpha\Gamma\alpha^{-1} \cap \Gamma, \quad \Gamma_\alpha = \alpha^{-1}\Gamma\alpha \cap \Gamma, \quad (23)$$

these are again congruence subgroups. The isomorphism $[\alpha] : \Gamma_\alpha \rightarrow \Gamma^\alpha : \gamma \mapsto \alpha\gamma\alpha^{-1}$ induces an isomorphism $\Gamma_\alpha \backslash \mathfrak{H}^* \rightarrow \Gamma^\alpha \backslash \mathfrak{H}^*$. The inclusions $\Gamma_\alpha, \Gamma^\alpha \subseteq \Gamma$ induce finite unramified coverings of Riemann surfaces $\Gamma_\alpha \backslash \mathfrak{H}^*, \Gamma^\alpha \backslash \mathfrak{H}^* \rightarrow \Gamma \backslash \mathfrak{H}^*$. Therefore, we obtain a trace map on cohomology, and the composite

$$H_{\text{Betti}}^1(X, A) \xrightarrow{\text{Res}} H_{\text{Betti}}^1(\Gamma^\alpha \backslash \mathfrak{H}^*, A) \xrightarrow{[\alpha]^*} H_{\text{Betti}}^1(\Gamma_\alpha \backslash \mathfrak{H}^*, A) \xrightarrow{\text{tr}} H_{\text{Betti}}^1(X, A) \quad (24)$$

is an A -linear map depending only on the double coset $\Gamma\alpha\Gamma$; here A is an arbitrary abelian group. If A is a $\text{GL}_2(\mathbb{Q})$ -equivariant local system we include an isomorphism $\alpha_* A \cong A$ in the composite (24). This operator is notated $[\Gamma\alpha\Gamma]$. For $f \in \mathcal{S}_k(\Gamma)$ or $\mathcal{M}_k(\Gamma)$ we define $f[\Gamma\alpha\Gamma]_k := \sum_j f|_k \beta_j$ where $\Gamma\alpha\Gamma = \bigsqcup_j \Gamma\beta_j$ is a system of coset representatives.

Since $\Gamma_1(N) \trianglelefteq \Gamma_0(N)$ the quotient $\Gamma_0(N)/\Gamma_1(N) = (\mathbb{Z}/N\mathbb{Z})^\times$ acts on $\Gamma_1(N)$ by conjugation. Hence in the above discussion, taking $\alpha \in \Gamma_0(N)$ and $\Gamma = \Gamma_1(N)$, induces an action of $(\mathbb{Z}/N\mathbb{Z})^\times$ on $H_{\text{Betti}}^1(X, A)$ and $\mathcal{S}_k(\Gamma_1(N))$. The operator induced by $d \in (\mathbb{Z}/N\mathbb{Z})^\times$ is denoted $\langle d \rangle_k$. Also, if one takes $\alpha = \begin{pmatrix} 1 & 0 \\ 0 & p \end{pmatrix}$ (and $\Gamma = \Gamma_1(N)$), the resulting operators on $H_{\text{Betti}}^1(X, A)$ and $\mathcal{S}_k(\Gamma_1(N))$ are denoted T_p . Let \mathbb{T}_k denote the subring of $\text{End}(\mathcal{S}_k(\Gamma_1(N)))$ generated by $\{\langle q \rangle_k, T_p : q, p \nmid N\}$. Let $R(\Gamma_1(N))$ be the subring of $\text{End}(H_{\text{Betti}}^1(X, \text{Sym}^{k-2}\mathbb{Z}^2))$ generated by $\{\langle q \rangle_k, T_p : q, p \nmid N\}$. By definition, we see that $R(\Gamma_1(N))$ is a finite \mathbb{Z} -module. Moreover, the Eichler-Shimura isomorphism is equivariant for these Hecke actions in the sense that, via (22), the action of $R(\Gamma_1(N))$ on $H_{\text{Betti}}^1(X, \text{Sym}^{k-2}\mathbb{Z}^2)$ induces an action on $\mathcal{S}_k(\Gamma_1(N))$ which agrees with \mathbb{T}_k . It follows that

Corollary 3.1. \mathbb{T}_k is a finite free \mathbb{Z} -module.

The elements of \mathbb{T}_k are commuting linear operators on $\mathcal{S}_k(\Gamma_1(N))$, and normal with respect to the Petersson inner product. Therefore

$$\mathcal{S}_k(\Gamma_1(N)) = \bigoplus_\lambda \mathcal{S}_k(\Gamma_1(N))_\lambda, \quad (25)$$

over all systems of eigenvalues $\lambda : \mathbb{T}_k \rightarrow \mathbb{C}$. Therefore, choosing a simultaneous basis of eigenforms simultaneously diagonalises the operators \mathbb{T}_k and defines an algebra isomorphism $\mathbb{T}_k \otimes_{\mathbb{Z}} \mathbb{C} \cong \mathbb{C}^{\#\{\text{distinct } \lambda\}}$. Since \mathbb{T}_k is free, $\mathbb{T}_k \hookrightarrow \mathbb{T}_k \otimes \mathbb{C}$ and so it is reduced. Corollary

¹This is my (made-up) notation.

3.1 implies that $\mathbb{Z} \rightarrow \mathbb{T}_k$ is an integral extension and since \mathbb{Z} is an integrally closed domain this extension satisfies going-up and going-down. In particular the minimal primes of \mathbb{T}_k are precisely the finitely many $\mathfrak{p} \subseteq \mathbb{T}_k$ lying above 0. Since $\mathbb{T}_k \otimes_{\mathbb{Z}} \mathbb{Q}$ is a finite \mathbb{Q} -algebra, it has a canonical decomposition

$$\mathbb{T}_k \otimes_{\mathbb{Z}} \mathbb{Q} \cong \prod_{\mathfrak{p}} K_{\mathfrak{p}}, \quad (26)$$

where the fields $K_{\mathfrak{p}}$ are the localisations of \mathbb{T}_k at these minimal primes. These primes can be identified with the kernels of homomorphisms $\lambda : \mathbb{T}_k \rightarrow \overline{\mathbb{Q}}$, which determines λ up to $\text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ -conjugacy². In turn we can choose a unique normalised newform $f \in \mathcal{S}_k(\Gamma_1(M))$ (for some $M|N$), for λ . In summary the following finite sets are in natural bijection:

- Minimal primes of \mathbb{T}_k .
- Maximal ideals of $\mathbb{T}_k \otimes_{\mathbb{Z}} \mathbb{Q}$.
- $\text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ -conjugacy classes of normalised newforms in $\mathcal{S}_k(\Gamma_1(M))$, where $M|N$.
